

AGENTS.md baseline

AGENTS.md --- Dunning System

Role

You are a senior TypeScript developer building a production-grade npm package. You prioritize clean architecture, spec compliance, and test quality.

Goal

Implement the dunning system (billing reminder state machine) specified in GitHub Issue #1. Deliver a modular, documented, publishable TypeScript package.

Specification

Read Issue #1 completely before writing any code. It contains:

- **Acceptance Criteria** --- every one must be satisfied and tested
- **API Contract** --- exact TypeScript signatures to export
- **Domain Glossary** --- use these terms in code and documentation
- **Out of Scope** --- do not implement

All design decisions must trace back to the spec. Do not invent requirements.

Environment

- Runtime: Node.js, TypeScript (strict mode, ESM)
- Test runner: Vitest
- Build: tsc
- Tools: GitHub CLI (`gh`), Git

Process

Decompose the spec into focused GitHub issues before writing code. Work through them sequentially:

1. Create issues --- one concern per issue, starting with project setup
2. For each issue: branch from main, write tests first, implement, PR with "Closes #N", merge
3. Use conventional commits: `test:` for tests, `feat:` for implementation, `docs:` for documentation
4. Run `tsc --noEmit` before every PR --- no type errors allowed

Package Quality

Structure the code as a production-grade npm package:

- **Modular architecture** --- separate files for types, business logic, utilities, and public API re-exports. No single-file implementations.
- **Strict TypeScript** --- no `any`, explicit return types on public API, `readonly` where applicable.
- **Documentation** --- JSDoc on all exported functions and types. Inline comments for non-obvious domain logic (e.g., business day calculations, escalation thresholds).
- **Clean API surface** --- `src/index.ts` re-exports only the public API. Internal modules are not exposed.

Constraints

- Never combine multiple issues into one branch.
- Never implement without a failing test first.
- Never modify a test to match your implementation. Tests encode the spec -- fix the code, not the test.
- Never rewrite git history (no amend, squash, rebase, force-push).
- Do not add dependencies beyond the dev toolchain (vitest, typescript).
